Cheat Sheet: Python Data Structures Part-2

Dictionaries

Package/Method	Description	Code Example
Creating a Dictionary	A dictionary is a built-in data type that represents a collection of key-value pairs. Dictionaries are enclosed in curly braces {}.	Example: 1. 1 2. 2
		<pre>1. dict_name = {} #Creates an empty dictionary 2. person = { "name": "John", "age": 30, "city": "New York"}</pre>
Accessing Values	You can access the values in a dictionary using their corresponding keys.	Copied!
		1. 1
		<pre>1. Value = dict_name["key_name"] Copied!</pre>
		Example:
		1. 1 2. 2
		<pre>1. name = person["name"] 2. age = person["age"]</pre>
		Copied! Syntax:
		 1. 1 1. dict_name[key] = value
	Inserts a new key-value pair into the dictionary. If the key already exists, the value will be updated; otherwise, a new entry is created.	Copied!
Add or modify		Example: 1. 1
		 2. 2 person["Country"] = "USA" # A new entry will be created.
		<pre>2. person["city"] = "Chicago" # Update the existing value for the same key</pre>
		Syntax: 1. 1
	Removes the specified key-value pair from the dictionary. Raises a KeyError if the key does not exist.	1. del dict_name[key]
del		Copied! Example:
		1. 1
		1. del person["Country"] Copied!
		Syntax: 1. 1
		<pre>1. dict_name.update({key: value})</pre>
update()	The update() method merges the provided dictionary into the existing dictionary, adding or updating key-value pairs.	Example:
clear()	The clear() method empties the dictionary, removing all key-value pairs within it. After this operation, the dictionary is still accessible and can be used further.	1. 1
		<pre>1. person.update({"Profession": "Doctor"}) Copied!</pre>
		Syntax: 1. 1
		1. dict_name.clear()
		Copied! Example:
		1. 1
		1. grades.clear()

		Copied! Example:
key existence	You can check for the existence of a key in a dictionary using the in keyword	1. 1 2. 2
		 if "name" in person: print("Name exists in the dictionary.")
		Copied! Syntax:
	Creates a shallow copy of the dictionary. The new dictionary contains the same key-value pairs as the original, but they remain distinct objects in memory.	1. 1
		1. new_dict = dict_name.copy()
		Copied!
copy()		Example:
		1. 1 2. 2
		 new_person = person.copy() new_person = dict(person) # another way to create a copy of dictionary
		Copied! Syntax:
		1. 1
	Retrieves all keys from the dictionary and converts them into a list. Useful for iterating or processing keys using list methods.	<pre>1. keys_list = list(dict_name.keys())</pre>
		Copied!
keys()		Example:
		1. 1
		<pre>1. person_keys = list(person.keys())</pre>
		Copied!
	Extracts all values from the dictionary and converts them into a list. This list can be used for further processing or analysis.	Syntax:
		1. 1
		1. values_list = list(dict_name.values())
values()		
		Example:
		<pre>1. 1 1. person_values = list(person.values())</pre>
		Copied!
	Retrieves all key-value pairs as tuples and converts them into a list of tuples. Each tuple consists of a key and its corresponding value.	Syntax:
		1. 1
		<pre>1. items_list = list(dict_name.items())</pre>
items()		Copied!
		Example:
		1. 1
		1. info = list(person.items())
		Copied!

Sets

Package/Method	d Description	Code Example
		Syntax:
		1. 1
add()	Elements can be added to a set using the `add()` method. Duplicates are automatically removed, as sets only store unique values.	<pre>1. set_name.add(element)</pre>
		Copied!
		Example:
		1. 1
clear()	The `clear()` method removes all elements from the set, resulting in an empty set. It updates the set in-place.	 fruits.add("mango")
		Copied!
		Syntax:
		1. 1
		<pre>1. set_name.clear()</pre>

6/23/24, 12:10 PM about:blank

```
Copied!
                                                                                                          Example:
                                                                                                             1. 1
                                                                                                             1. fruits.clear()
                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                             1. new_set = set_name.copy()
                                                                                                           Copied!
                  The 'copy()' method creates a shallow copy of the set. Any modifications to the copy
copy()
                  won't affect the original set.
                                                                                                          Example:
                                                                                                             1. 1
                                                                                                             1. new_fruits = fruits.copy()
                                                                                                           Copied!
                                                                                                          Example:
                                                                                                             2. 2
                  A set is an unordered collection of unique elements. Sets are enclosed in curly braces
Defining Sets
                                                                                                             1. empty_set = set() #Creating an Empty
2. Set fruits = {"apple", "banana", "orange"}
                   `{}`. They are useful for storing distinct values and performing set operations.
                                                                                                          Copied!
                                                                                                          Syntax:

    set_name.discard(element)

                                                                                                           Copied!
                  Use the 'discard()' method to remove a specific element from the set. Ignores if the
discard()
                  element is not found.
                                                                                                          Example:
                                                                                                             1. 1

    fruits.discard("apple")

                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                             1. 1
                                                                                                             1. is_subset = set1.issubset(set2)
                                                                                                          Copied!
                  The 'issubset()' method checks if the current set is a subset of another set. It returns
issubset()
                  True if all elements of the current set are present in the other set, otherwise False.
                                                                                                          Example:
                                                                                                             1. 1
                                                                                                             1. is_subset = fruits.issubset(colors)
                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                          is superset = set1.issuperset(set2)
                  The 'issuperset()' method checks if the current set is a superset of another set. It
                                                                                                          Example:
                  returns True if all elements of the other set are present in the current set, otherwise
issuperset()
                  False.
                                                                                                             1. is_superset = colors.issuperset(fruits)
                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                             1. removed_element = set_name.pop()
                                                                                                          Copied!
                  The 'pop()' method removes and returns an arbitrary element from the set. It raises a
                  'KeyError' if the set is empty. Use this method to remove elements when the order
pop()
                                                                                                          Example:
                  doesn't matter.
                                                                                                             1. removed_fruit = fruits.pop()
                                                                                                           Copied!
                  Use the 'remove()' method to remove a specific element from the set. Raises a
remove()
                                                                                                          Syntax:
                   'KeyError' if the element is not found.
                                                                                                             1. 1
                                                                                                             1. set_name.remove(element)
                                                                                                           Copied!
```

Perform various operations on sets: 'union', 'intersection', 'difference', 'symmetric

The 'update()' method adds elements from another iterable into the set. It maintains

Example:

- 1. 1
- fruits.remove("banana")

Copied!

Syntax:

- 1. 1 2. 2 3. 3 4. 4

- 1. union_set = set1.union(set2)
 2. intersection_set = set1.intersection(set2)
 3. difference_set = set1.difference(set2)
 4. sym_diff_set = set1.symmetric_difference(set2)

Copied!

Example:

- 1. 1
- 2. 2 3. 3 4. 4
- 1. combined = fruits.union(colors)
- 2. common = fruits.intersection(colors)
- 3. unique_to_fruits = fruits.difference(colors)4. sym_diff = fruits.symmetric_difference(colors)

Copied!

Syntax:

- set_name.update(iterable)

Copied!

Example:

- 1. 1
- fruits.update(["kiwi", "grape"])

Copied!

the uniqueness of elements.
